

How to create a JavaFX in the labs

1. Create a new JavaFX project

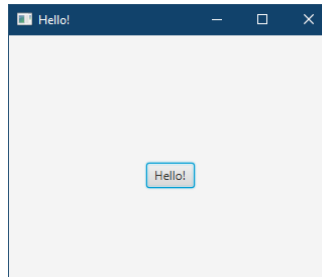

2. Choose which dependencies you want to have included. For this module, the ControlsFX dependency should be sufficient.

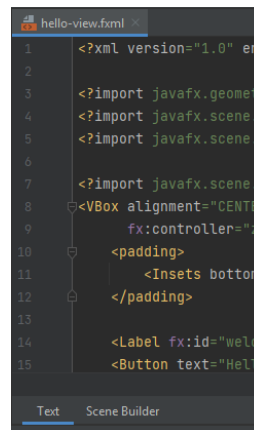

3. Wait for IntelliJ to download all the necessary dependencies.
4. Run the project by HelloApplication class and running its psvm method.

```
public static void main(String[] args) { launch(); }
```

5. The application should run after it has compiled.

6. If you are creating a UI in code (as in the earlier assignments and assessment), then delete the HelloController.java, hello-view.fxml files and edit the HelloApplication.java class to have the code you want.
7. If you are using FXML to create your UI using the drag-and-drop editor, then open the hello-view.fxml file and click on the SceneBuilder tab at the bottom.

- a. The first time on a particular computer you do this, you will get an error message and be given a choice to download the SceneBuilder Kit. Do so.
- b. Once the SceneBuilder Kit has been installed, you can edit the UI using the editor.
